# Study of Kovats Retention Indices of Polybrominated Diphenyl Ethers 

As Presented at the Poster Session at the BFR 2004 Conference.

Richard P. Kozloski, Anke Gelbin, Russ Cooper<br>AccuStandard, Inc. 125 Market Street New Haven, CT 06513 USA

## Introduction

Polybrominated diphenyl ethers (PBDEs) found in flame retardants are coming under increasing environmental scrutiny. They are gaining attention similar to that of polychlorinated biphenyls (PCBs) from several decades ago. PBDEs raise similar carcinogenic and toxicity concerns and are less well understood than their PCB analogues. Some PBDEs resist degradation and concentrate in adipose tissue, affecting endocrine and hepatic functions ${ }^{1}$. This paper will describe an effort to chromatograph and measure the retention time of over 130 different PBDE congeners in order to obtain their Kovats retention indices and thereby predict absolute and relative retention data for those PBDE congeners not yet commercially available to the scientific community.

## Methods and Materials

Analysis of PBDE congeners was performed by injecting $2 \mu \mathrm{~L}$ of 100 ppm solutions in isooctane. Chromatography was effected using an HP 5890 Series II Gas Chromatograph equipped with a $30 \mathrm{M} \times 0.53 \mu \mathrm{M}$ DB-5 ( $5 \%$ phenyl $95 \%$ methyl silicone) capillary column fitted to a flame ionization detector. Injector, detector, and oven temperatures were chosen for sufficient volatilization of the analyte while maintaining gaussian peak shape and optimal resolution. The absolute retention times of over 130 PBDEs were obtained using the conditions described above and compared to the retention times of octachloronaphthalene and the n-alkanes which elute over the range of the PBDEs. Kovats retention indices were determined for each PBDE peak from the interpolation of n-alkane retention times in the linear temperature programming region of the chromatograms. The Kovats indices were used to determine absolute retention times for as many unavailable PBDE congeners as possible. Retention data was recorded and presented in tabular form (see Table 1).

## Results and Discussion

The contribution of each phenyl ring to the Kovats retention indices of the PBDEs was determined by taking half the Kovats retention indices of a subset of the symmetrical ethers. These values were then applied to asymmetrical PBDEs to obtain data for phenyl rings with other substitution patterns. The data was checked for internal consistency by calculating the contribution of each type of ring pattern from a variety of different ethers and appropriate adjustments were made to the values of the contributing ring indices. These values were then used to calculate the Kovats retention indices of unavailable
ethers within the linear programming range of the GC runs. PBDEs with 2,3,5; 2,3,6 and 2,3,5,6 ring distribution patterns were not included because of the lack of availability of PBDEs having these substitution patterns. The summation of Kovats retention indices in this manner has been used successfully in predicting the retention times (RT) of PCB congeners ${ }^{2}$. However, the Kovats indices of PCBs which are highly chlorinated in the ortho positions are temperature dependent due to the sterically hindered rotation of the rings. With the bridging oxygen in the PBDEs, it was expected that the ring steric hindrance could be overcome despite the presence of bromine substituents. PBDEs containing only mono and dibrominated phenyl groups had a fair degree of predictability except for some instances where there were three or more ortho bromines. Surprisingly, ethers having an unsubstituted ring showed only moderately predictable Kovats indices. This may have been due to the relatively high electron density of the pi electrons interacting with the bromine atoms on the adjacent phenyl ring. All of the PBDEs containing a tribrominated ring tended to have retention times that were difficult to predict with the exception of those with a 2,4,5 ring. Compounds with a 2,3,4,5 brominated ring had fair RT predictability and those with 2,3,4,6 and 2,3,4,5,6 substitution had poor RT predictability. A consequence of the steric hindrance in the rotation of the rings of PBDE congeners is that the relative retention times can shift as a function of temperature. Changes in analysis conditions can potentially result in the reversal of the elution order of closely spaced peaks, rendering the PBDE identification suspect.

## Conclusions

The precedence of using Kovats indices for successfully predicting analytical retention times and thereby the identities of many PCB congeners had led us to expect similar success with PBDEs. Having synthesized over half of all 209 PBDE congeners it was hoped, by using Kovats retention index data, that we would be able to predict with a high degree of accuracy where we would expect to find the unavailable congeners in a temperature programmed gas chromatographic analysis. Such was not always the case. This study has demonstrated that without a diverse range of PBDE congeners with different substitution patterns, retention data and therefore the identity of the unavailable PBDEs is difficult to establish.
